Interval Codes (Recap)

Shannon-Fano-Elias Coding method:

- Order the alphabet A.
- Represent distribution **p** by cumulative distribution F
- Construct code by finding intervals of width $\frac{p_i}{2}$ that lie in each symbol interval $[F(a_{i-1}), F(a_i))$

Intervals and Prefix Codes (Recap)

The set of numbers in [0,1) that start with a given sequence of bits $\mathbf{b} = b_1 \dots b_n$ form the interval

$$\left[0.b_{1} \ldots b_{n}, 0.b_{1} \ldots b_{n} + \frac{1}{2^{n}}\right) = \left[0.b_{1} \ldots b_{n}, 0.b_{1} \ldots b_{n} + 0.0 \ldots 1\right)$$

This interval contains all binary strings for which $b_1b_2...b_n$ is a prefix

Prefix property (interval form): Once you pick a codeword $b_1b_2 \dots b_n$, you cannot pick any codeword in the codeword interval

$$\left[0.b_1b_2...b_n, 0.b_1b_2...b_n + \frac{1}{2^n}\right)$$

Interval Coding Blocks

What if we apply SFE coding to blocks of an ensemble X?

Example: Let $A = \{aa, ab, ba, bb\}$ with p = (0.2, 0.6, 0.1, 0.1).

Interval Coding Blocks

What if we apply SFE coding to blocks of an ensemble X?

Example: Let $A = \{aa, ab, ba, bb\}$ with p = (0.2, 0.6, 0.1, 0.1).

X	p	Ē	$ar{\mathcal{F}}_2$	ℓ	Code
aa	0.2	0.1	$0.0\overline{0011}_{2}$	4	0001
ab	0.6	0.5	0.12	2	10
ba	0.1	0.85	$0.110\overline{1100}_{2}$	5	11011
bb	0.1	0.95	$0.11\overline{1100}_{2}$	5	11110

Extend to longer sequences

Interval Coding Blocks

What if we apply SFE coding to blocks of an ensemble *X*?

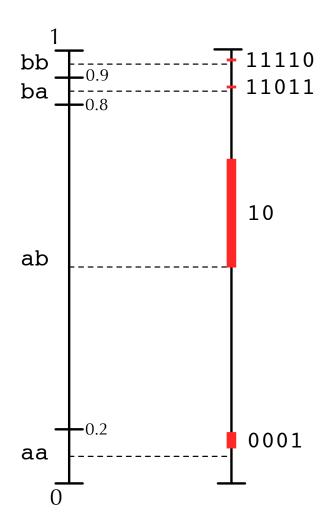

Example: Let $A = \{aa, ab, ba, bb\}$ with p = (0.2, 0.6, 0.1, 0.1).

X	p	Ē	$ar{\mathcal{F}}_2$	ℓ	Code
aa	0.2	0.1	$0.0\overline{0011}_{2}$	4	0001
ab	0.6	0.5	0.12	2	10
ba	0.1	0.85	$0.110\overline{1100}_{2}$	5	11011
bb	0.1	0.95	$0.11\overline{1100}_{2}$	5	11110

Extend to longer sequences

This works but:

- Need $P(\mathbf{x})$ for all \mathbf{x}
- Total $|A|^N$ values for length N
- Huffman has similar complexity but shorter codes.

Arithmetic Coding: A Bird's Eye View

Basic idea of arithmetic coding follows SFE coding

	SFE Coding	Arithmetic coding
Input	Single outcome x _i	Sequence of outcomes $X_1 X_2 \dots X_N$
Key step	Find symbol interval for x_i	Find symbol interval for $X_1 X_2 \dots X_N$
Output	Binary string corresponding to chosen interval	Binary string corresponding to chosen interval

Arithmetic Coding: A Bird's Eye View

Basic idea of arithmetic coding follows SFE coding

	SFE Coding	Arithmetic coding
Input	Single outcome x _i	Sequence of outcomes
		$X_1X_2\ldots X_N$
Key step	Find symbol interval for x_i	Find symbol interval for $X_1 X_2 \dots X_N$
	Use $[F(x_{i-1}), F(x_i))$?
Output	Binary string corresponding to chosen interval	Binary string corresponding to chosen interval
	Output first $\ell(x_i)$ bits of midpoint of interval	Output first $\ell(x_1 x_2 \dots x_N)$ bits of midpoint of interval

Arithmetic Coding: Summary

Arithmetic coding has some important properties:

- We do not compute a symbol coding for X and then concatenate
 - Directly work with blocks of size N
- We do not explicitly code all length N sequences at once
 - Highly efficient
- We do not assume that each of the x_i 's is **independent**
 - Not restricted to extended ensembles
 - Adapts to data distribution

- From SFE to Arithmetic Coding
- Arithmetic Coding: Encoder
 - Intervals for Sequences
 - Codeword Generation
 - Putting it all together
- 3 Arithmetic Coding: Decoder
- Adapting Distributions On-The-Fly

Say N = 2 and we want to code $x_1 x_2$

Ideally, we'd like to compute $p(\mathbf{x})$ for all possible \mathbf{x} of length 2, and then find the interval for $p(x_1x_2)$

Key ideas:

- we can write $p(x_1x_2) = p(x_1)p(x_2|x_1)$
 - decompose joint into conditional probabilities

Say N = 2 and we want to code $x_1 x_2$

Ideally, we'd like to compute $p(\mathbf{x})$ for all possible \mathbf{x} of length 2, and then find the interval for $p(x_1x_2)$

Key ideas:

- we can write $p(x_1x_2) = p(x_1)p(x_2|x_1)$
 - decompose joint into conditional probabilities
- $p(\cdot|x_1)$ is just another probability distribution
 - so we can compute intervals as per SFE

Say N = 2 and we want to code $x_1 x_2$

Ideally, we'd like to compute $p(\mathbf{x})$ for all possible \mathbf{x} of length 2, and then find the interval for $p(x_1x_2)$

Key ideas:

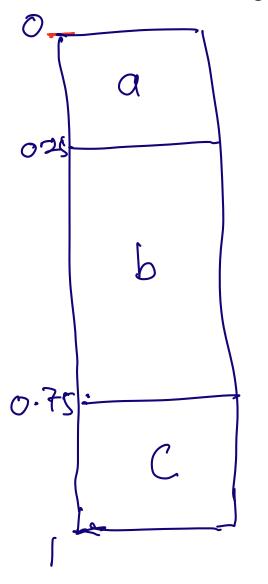

- we can write $p(x_1x_2) = p(x_1)p(x_2|x_1)$
 - decompose joint into conditional probabilities
- $p(\cdot|x_1)$ is just another probability distribution
 - so we can compute intervals as per SFE
- we can find an interval for $p(x_2|x_1)$ within the interval for x_1
 - normal SFE computes the interval within [0, 1) by default

Example: Suppose $A = \{a, b, c\}$ and p(a) = 0.25, p(b) = 0.5, p(c) = 0.25

Like with SFE coding, we'd begin by slicing up [0, 1) into three subintervals:

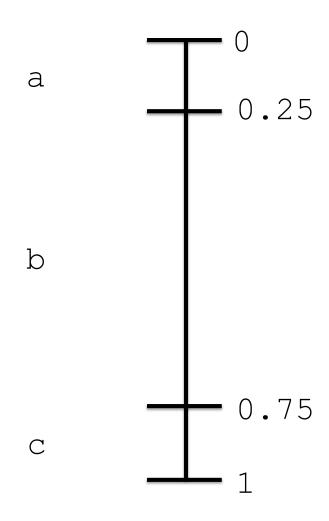

Example: Suppose $A = \{a, b, c\}$ and p(a) = 0.25, p(b) = 0.5, p(c) = 0.25

Like with SFE coding, we'd begin by slicing up [0, 1) into three subintervals:

Example: Suppose $A = \{a, b, c\}$ and p(a) = 0.25, p(b) = 0.5, p(c) = 0.25

Like with SFE coding, we'd begin by slicing up [0, 1) into three subintervals:

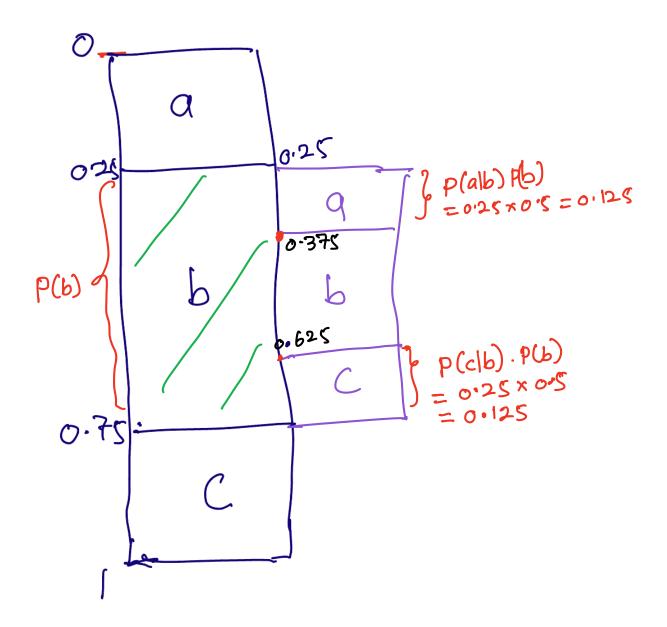

So e.g. we treat [0.25, 0.75) as the interval for b

Suppose the first symbol is b, and p(a|b) = 0.25, p(b|b) = 0.5, p(c|b) = 0.25

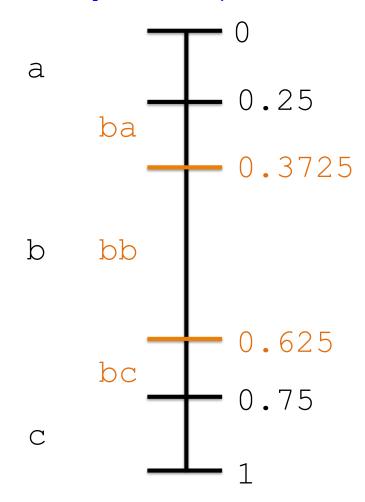

To code ba, bb, bc, now slice up [0.25, 0.75), the interval for b itself:

Suppose the first symbol is b, and p(a|b) = 0.25, p(b|b) = 0.5, p(c|b) = 0.25

Suppose the first symbol is b, and p(a|b) = 0.25, p(b|b) = 0.5, p(c|b) = 0.25

To code ba, bb, bc, now slice up [0.25, 0.75), the interval for b itself:

For ba we choose the interval of length p(a|b) = 0.25 times the length of the enclosing interval (0.75 - 0.25 = 0.5), i.e. (0.25)(0.5) = 0.125

Arithmetic Coding: End of Stream Symbol

It is convenient to explicitly have a special "end of stream" symbol, \square

We add this symbol to our ensemble, with some suitable probability

- e.g. $p(\Box)$ = probability of seeing empty string, $p(\Box|a)$ = probability of seeing just the string a, etc
- Implicitly we think of ab as actually being ab

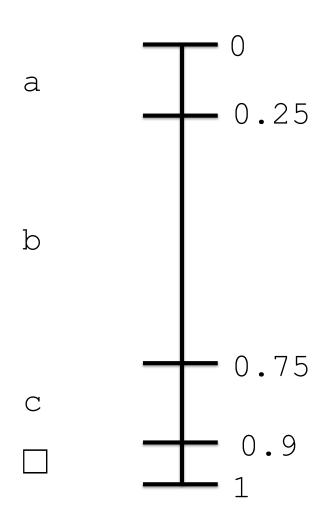

End of stream is by definition reached when we choose the sub-interval for this special symbol

Example: Suppose $A = \{a, b, c, \Box\}$ and $p(a) = 0.25, p(b) = 0.5, p(c) = 0.15, p(\Box) = 0.1$

Like with SFE coding, we'd begin by slicing up [0, 1) into three subintervals:

Example: Suppose
$$A = \{a, b, c, \Box\}$$
 and $p(a) = 0.25, p(b) = 0.5, p(c) = 0.15, p(\Box) = 0.1$

Like with SFE coding, we'd begin by slicing up [0, 1) into three subintervals:

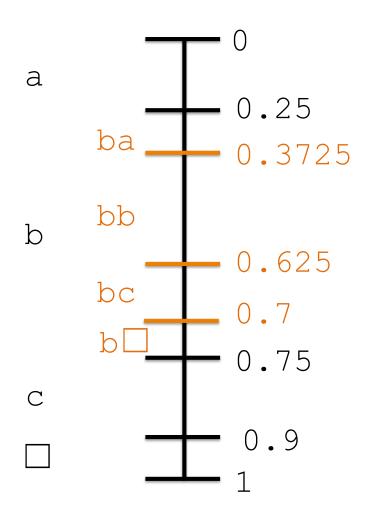

Now suppose that $p(\cdot|b)$ stays the same as $p(\cdot)$

If the first symbol is b, we carve the interval for b into four pieces:

Now suppose that $p(\cdot|b)$ stays the same as $p(\cdot)$

If the first symbol is b, we carve the interval for b into four pieces:

Exact same idea as before, just with special symbol \square

Arithmetic Coding for Arbitrary Sequences

These ideas generalise to arbitrary length sequences

• We don't even need to know the sequence length beforehand!

As we see more symbols, we slice the appropriate sub-interval of [0, 1) based on the probabilities

■ Terminate whenever we see □

Arithmetic Coding: Codeword Generation

Once we've seen the entire sequence, we end up with interval [u, v)

• How to output a codeword?

Arithmetic Coding: Codeword Generation

Once we've seen the entire sequence, we end up with interval [u, v)

• How to output a codeword?

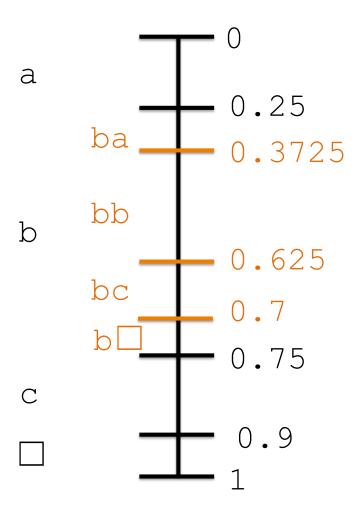

As per SFE coding, we can use the first $\ell(x_1x_2...x_N)$ bits of (u+v)/2

- Here, $\ell(x_1 x_2 ... x_N) = \lceil \log 1/p(x_1 x_2 ... x_N) \rceil + 1$
- As before, this guarantees all strings starting with codeword are contained in the codeword interval

Generally, we can output some bits on the fly, rather than wait till we process the entire sequence

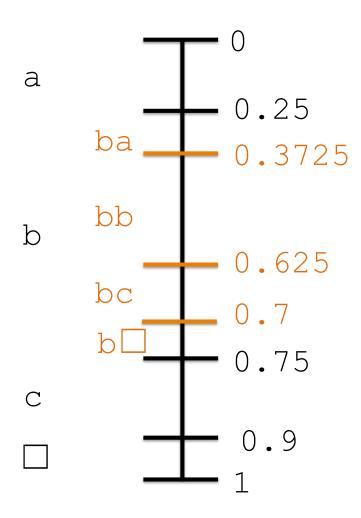

Arithmetic Coding: Codeword Generation Example

In previous example with input b, we'd stop in the interval for $b\Box$, i.e. [0.7, 0.75)

Arithmetic Coding: Codeword Generation Example

In previous example with input b, we'd stop in the interval for $b\Box$, i.e. [0.7, 0.75)

Midpoint is $0.725 = 10111\overline{0011}$, and $p(b\Box) = (1/2) \cdot (0.1) = 0.05$

Output the first $\lceil \log_2 1/0.05 \rceil + 1 = 6$ bits, i.e. 101110

Arithmetic Coding: Formal Encoder

Formally, we compute the interval [u, v) for a generic sequence as follows:

Arithmetic Coding of stream $x_1 x_2 \dots$

```
u \leftarrow 0.0
v \leftarrow 1.0
p \leftarrow v - u
```

for
$$n = 1, 2, ...$$

- Compute $L_n(a_i|x_1,...,x_{n-1}) = \sum_{i'=1}^{i-1} p(x_n = a_{i'}|x_1,...,x_{n-1})$
- Compute $U_n(a_i|x_1,...,x_{n-1}) = \sum_{i'=1}^i p(x_n = a_{i'}|x_1,...,x_{n-1})$
- \bullet $v \leftarrow u + p \cdot U_n(x_n|x_1,...,x_{n-1})$
- $u \leftarrow u + p \cdot L_n(x_n|x_1,...,x_{n-1})$
- \bullet $p \leftarrow v u$
- if $x_n = \square$, terminate

Output first $\ell(x_1x_2...x_N) = \lceil \log 1/p \rceil + 1$ bits of (u+v)/2

Here, L_n , U_n just compute the appropriate lower and upper bounds, as per SFE coding

We rescale these based on the current interval length

 - Codeword Generation
 - Putting it all together
- 3 Arithmetic Coding: Decoder
- Adapting Distributions On-The-Fly

Decoding

How do we decode a sequence of bits?

Rough Sketch:

- Carve out [0, 1) based on initial distribution
- Keep reading bits until current code interval in a symbol interval
- Output that symbol
- Carve out appropriate interval based on probabilities

We can stop once we have containment in interval for \Box

Suppose $p(a) = 0.5, p(b) = 0.125, p(c) = 0.25, p(\Box) = 0.125$ for every outcome in sequence

Adaptive Probabilities

So far we assume the sequence of probabilities are given in advance

In **Lecture 5**, you saw Bernoulli distribution for two outcomes

Adaptive Probabilities

So far we assume the sequence of probabilities are given in advance

In **Lecture 5**, you saw Bernoulli distribution for two outcomes

- Beta distribution Beta $(\theta|m_h, m_t)$ as a prior for Bern $(x|\theta)$
- The posterior after observing n_h heads and n_t tails is just Beta $(\theta|m_h + n_h, m_t + n_t)$
- The expected value of θ under the posterior is

$$p(x = h|n_h, n_t, m_h, m_t) = \frac{m_h + n_h}{m_h + n_h + m_t + n_t}$$

Dirichlet Model

A **Dirichlet distribution** is a generalisation of the Beta distribution to more than two outcomes. Its parameter is a vector $\mathbf{m} = (m_1, \dots, m_K)$ can be viewed as "virtual counts" for each symbol a_1, \dots, a_K :

$$P(x = a_i | x_1 \dots x_n) = \frac{\sharp(a_i) + m_i}{\sum_{k=1}^K \sharp(a_k) + m_k}$$

Can implement an adaptive guesser by just counting symbol occurrences.

Dirichlet Model

A **Dirichlet distribution** is a generalisation of the Beta distribution to more than two outcomes. Its parameter is a vector $\mathbf{m} = (m_1, \dots, m_K)$ can be viewed as "virtual counts" for each symbol a_1, \dots, a_K :

$$P(x = a_i | x_1 \dots x_n) = \frac{\sharp(a_i) + m_i}{\sum_{k=1}^K \sharp(a_k) + m_k}$$

Can implement an adaptive guesser by just counting symbol occurrences.

Flexible

- e.g., Choose **m** to be frequency of English letters
- $\sum_k m_k$ Large = Stable; Small = Responsive

title

Example: Start with $m_h = m_t = 1$ and observe sequence hht.

$$p(\cdot|\epsilon) = (\frac{1}{2}, \frac{1}{2}), p(\cdot|h) = (\frac{2}{3}, \frac{1}{3}), p(\cdot|hh) = (\frac{3}{4}, \frac{1}{4}) p(\cdot|hht) = (\frac{3}{5}, \frac{2}{5})$$

viz. Laplace's Rule, where ϵ means empty string

Why? Because e.g.

$$p(h|h) = \frac{1+1}{1+0+1+1} = 2/3$$

$$p(t|h) = \frac{0+1}{1+0+1+1} = 1/3$$

We'll assume this learning is only for non □ symbols

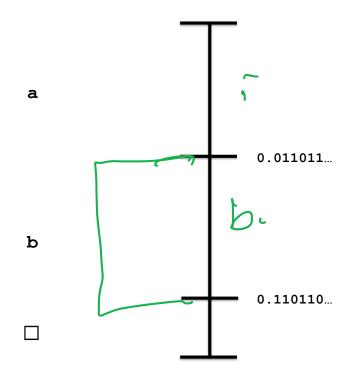

assume
 occurs with fixed probability each time

Possible outcomes a, b, □

Sequence: ϵ

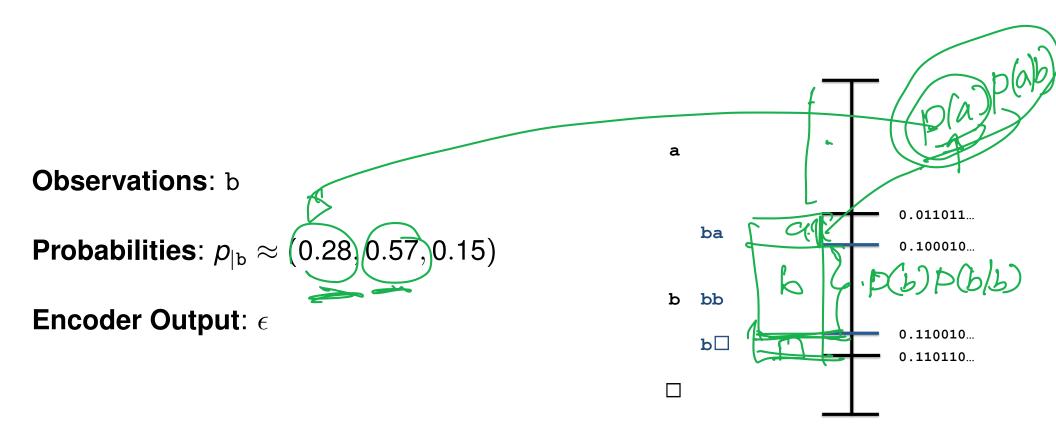

Probabilities: $p_{|\epsilon} = (0.425, 0.425, 0.15)$

Encoder: ϵ

We start off with virtual counts $m_{\rm a}=m_{\rm b}=1$

Possible outcomes a, b, □

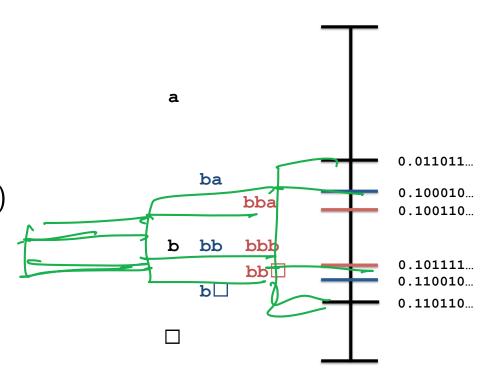

Seeing b makes us update $p(a|b) = (0.85) \cdot (1/3) \approx 0.28$, and $p(b|b) = (0.85) \cdot (2/3) \approx 0.57$. We keep $p(\Box|b) = p(\Box)$.

Possible outcomes a, b, □

Observations: bb

Probabilities: $p_{|bb} \approx (0.21, 0.64, 0.15)$

Encoder Output: 1

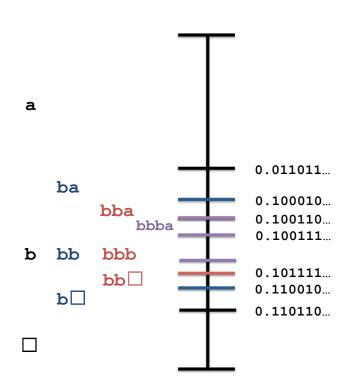

Seeing bb makes us update $p(a|bb)=(0.85)\cdot(1/4)\approx 0.21$, and $p(b|bb)=(0.85)\cdot(3/4)\approx 0.64$ Now the first bit is unambiguously 1

Possible outcomes a, b, □

Observations: bbb

Probabilities: $p_{|bbb} \approx (0.17, 0.68, 0.15)$

Encoder Output: 1

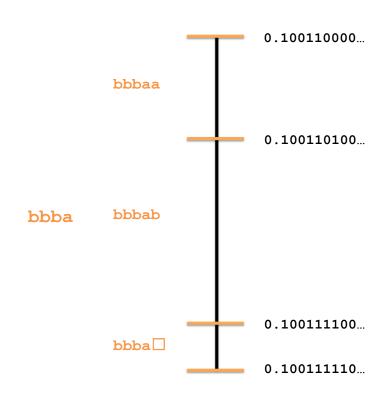

Possible outcomes a, b, □

Observations: bbba

Probabilities: $p_{|bbba} \approx (0.28, 0.57, 0.15)$

Encoder Output: 1001

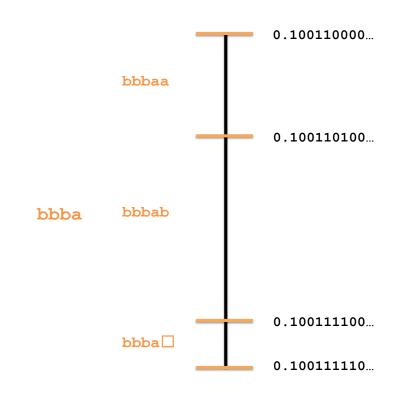

On seeing a, we can fill in three further bits unambiguously

Possible outcomes a, b, □

Observations: bbba□

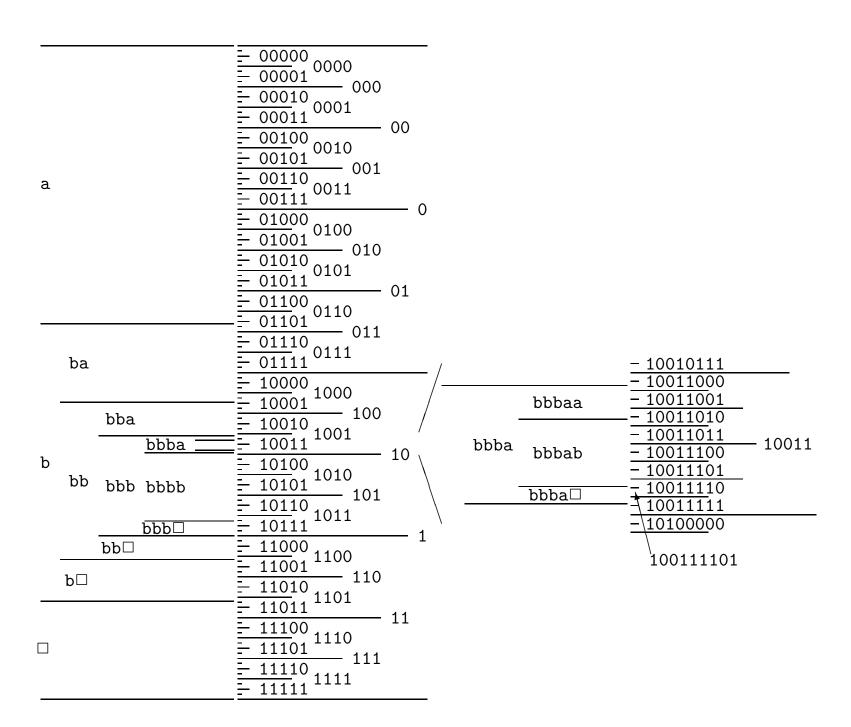

Probabilities: N/A

Encoder Output: 100111101

To terminate, we find midpoint of 0.100111100... and 0.100111110...

Arithmetic Coding: Example (MacKay, Figure 6.4)

Summary and Reading

Main Points

- Arithmetic Coding:
 - Uses interval coding and conditional probability
 - Separates coding and prediction
 - No need to compute every code word
- Predictive distributions:
 - Update distribution after each symbol
 - Beta and Dirichlet priors = virtual counts

Reading

Section 6.2 of MacKay
