#### Last time

• Markov's inequality: For a nonnegative RV X and for any  $\lambda > 0$ ,

$$p(X \ge \lambda) \le \frac{\mathbb{E}[X]}{\lambda}$$

• Chebyshev's inequality: RV X with  $\mathbb{E}[X] < \infty$  and for any  $\lambda > 0$ ,

$$p(|X - \mathbb{E}[X]| \ge \lambda) \le \frac{\mathbb{V}[X]}{\lambda^2}$$

Law of large numbers

## Law of Large Numbers

#### Theorem

Let  $X_1, \ldots, X_n$  be a sequence of iid random variables, with

$$\mathbb{E}[X_i] = \mu$$

and  $\mathbb{V}[X_i] < \infty$ . Define

$$\bar{X}_n = \frac{X_1 + \ldots + X_n}{n}.$$

Then, for any  $\beta > 0$ ,

$$\lim_{n\to\infty} p(|\bar{X}_n - \mu| < \beta) = 1.$$

This is also called  $\bar{X}_n \to \mu$  in probability.

**Definition**: For random variables  $v_1, v_2, ...$ , we say  $v_n \to v$  in probability if for all  $\beta > 0$   $\lim_{n \to \infty} P(|v_n - v| > \beta) = 0$ .

 $\beta$  is fixed (not shrinking like  $\frac{1}{n}$ ). Not max/min. Reduction in variability.

Typical sets

Asymptotic Equipartition Property (AEP)

- Ensembles and sequences
  - Counting Types of Sequences

- 2 Typical sets
- 3 Asymptotic Equipartition Property (AEP)
- Wrapping Up

#### **Ensembles**

#### Ensemble

An ensemble X is a triple  $(x, A_X, \mathcal{P}_X)$ ; x is a random variable taking values in  $A_X = \{a_1, a_2, \dots, a_l\}$  with probabilities  $\mathcal{P}_X = \{p_1, p_2, \dots, p_l\}$ .

We will call  $A_X$  the alphabet of the ensemble

#### Ensembles

Example: Bent Coin

Let X be an ensemble with outcomes h for heads with probability 0.9 and t for tails with probability 0.1.

- The outcome set is  $A_X = \{h, t\}$
- The probabilities are

$$\mathcal{P}_X = \{ p_h = 0.9, p_t = 0.1 \}$$

We can also consider blocks of outcomes, which will be useful to describe sequences:

#### **Example** (Coin Flips):

We can also consider blocks of outcomes, which will be useful to describe sequences:

#### Example (Coin Flips):

$\mathtt{hhhhthhthh} \to \mathtt{hh}$	hh	th	ht	ht	hh	$(6 \times 2 \text{ outcome blocks})$
---------------------------------------	----	----	----	----	----	---------------------------------------

ightarrow hhh hth hth thh (4 imes 3 outcome blocks)

ightarrow hhhh thht hthh (3 imes 4 outcome blocks)

#### **Extended Ensemble**

Let X be a single ensemble. The **extended ensemble** of blocks of size N is denoted  $X^N$ . Outcomes from  $X^N$  are denoted  $\mathbf{x} = (x_1, x_2, \dots, x_N)$ . The **probability** of  $\mathbf{x}$  is defined to be  $P(\mathbf{x}) = P(x_1)P(x_2)\dots P(x_N)$ .

Example: Bent Coin

Let X be an ensemble with outcomes  $\mathcal{A}_X = \{\mathtt{h},\mathtt{t}\}$  with  $p_\mathtt{h} = 0.9$  and  $p_\mathtt{t} = 0.1$ .

Consider  $X^4$  – i.e., 4 flips of the coin.

 $\mathcal{A}_{X^4} = \{\mathtt{hhhh},\mathtt{hhht},\mathtt{hhth},\ldots,\mathtt{tttt}\}$ 

Example: Bent Coin

Let X be an ensemble with outcomes  $\mathcal{A}_X = \{\mathtt{h},\mathtt{t}\}$  with  $p_\mathtt{h} = 0.9$  and  $p_\mathtt{t} = 0.1$ .

Consider  $X^4$  – i.e., 4 flips of the coin.

 $\mathcal{A}_{X^4} = \{\mathtt{hhhh},\mathtt{hhht},\mathtt{hhth},\ldots,\mathtt{tttt}\}$ 

$$P(\text{hhhh}) = (0.9)^4 \approx 0.6561$$
  
 $P(\text{tttt}) = (0.1)^4 = 0.0001$   
 $P(\text{hthh}) = 0.9 \cdot 0.1 \cdot 0.9 \cdot 0.9 = (0.9)^3 (0.1) \approx 0.0729$   
 $P(\text{htht}) = 0.9 \cdot 0.1 \cdot 0.9 \cdot 0.1 = (0.9)^2 (0.1)^2 \approx 0.0081$ .

Example: Bent Coin

#### Entropy of extended ensembles

We can view  $X^4$  as comprising 4 independent random variables, based on the ensemble X

Entropy is additive for independent random variables

Thus,

$$H(X^4) = 4H(X) = 4.(-0.9 \log_2 0.9 - 0.1 \log_2 0.1) = 1.88$$
bits.

More generally,

$$H(X^N) = NH(X).$$

#### Criteria for dividing $2^N$ sequences into **types**

In the bent coin example,

$$(0.9)^{2}(0.1)^{2} = P(hhtt)$$

$$= P(htht)$$

$$= P(htth)$$

$$= P(thht)$$

$$= P(thht)$$

$$= P(thhh).$$

The order of outcomes in the sequence is irrelevant

Let X be an ensemble with alphabet  $A_X = \{a_1, \dots, a_l\}$ .

Let 
$$p(X = a_i) = p_i$$
.

For a sequence  $\mathbf{x} = x_1, x_2, \dots, x_N$ , how to compute  $p(\mathbf{x})$ ?

let  $n_i$  = # of times symbol  $a_i$  appears in  $\mathbf{x}$  (symbol count)

Given the  $n_i$ 's, we can compute the probability of seeing **x**:

$$P(\mathbf{x}) = P(x_1) \cdot P(x_2) \cdot \ldots \cdot P(x_N)$$
  
=  $P(a_1)^{n_1} \cdot P(a_2)^{n_2} \cdot \ldots \cdot P(a_l)^{n_l}$   
=  $p_1^{n_1} \cdot p_2^{n_2} \ldots p_l^{n_l}$ 

Sufficient statistics:  $\{n_1, n_2, \dots, n_l\}$ . Use it as a criteria of partitioning.

#### Sequence Types

Each unique choice of  $(n_1, n_2, \dots, n_l)$  gives a different type of sequence

- 4 heads, (3 heads, 1 tail), (2 heads, 2 tails), ...
- Sequences in each type are equiprobable.

For a given type of sequence how many sequences are there with these symbol counts?

# of sequences with 
$$n_i$$
 copies of  $a_i = \frac{N!}{n_1! n_2! \dots n_l!}$ 

$$\binom{N}{n_1} \binom{N-n_1}{n_2} \binom{N-n_1-n_2}{n_3} \dots$$

$$= \frac{N!}{n_1!(N-n_1)!} \cdot \frac{(N-n_1)!}{n_2!(N-n_1-n_2)!} \cdot \frac{(N-n_1-n_2)!}{n_3!(N-n_1-n_2-n_3)!} \dots$$

Example

#### Probability of types

Let 
$$A = \{a, b, c\}$$
 with  $P(a) = 0.2$ ,  $P(b) = 0.3$ ,  $P(c) = 0.5$ .

Example

#### Probability of **types**

Let 
$$A = \{a, b, c\}$$
 with  $P(a) = 0.2$ ,  $P(b) = 0.3$ ,  $P(c) = 0.5$ .

Each sequence of type  $(n_a, n_b, n_c) = (2, 1, 3)$  has length 6 and probability  $(0.2)^2(0.3)^1(0.5)^3 = 0.0015$ .

Example

#### Probability of types

Let 
$$A = \{a, b, c\}$$
 with  $P(a) = 0.2$ ,  $P(b) = 0.3$ ,  $P(c) = 0.5$ .

Each sequence of type  $(n_a, n_b, n_c) = (2, 1, 3)$  has length 6 and probability  $(0.2)^2(0.3)^1(0.5)^3 = 0.0015$ .

There are  $\frac{6!}{2!1!3!} = 60$  such sequences.

Example

#### Probability of types

Let 
$$A = \{a, b, c\}$$
 with  $P(a) = 0.2$ ,  $P(b) = 0.3$ ,  $P(c) = 0.5$ .

Each sequence of type  $(n_a, n_b, n_c) = (2, 1, 3)$  has length 6 and probability  $(0.2)^2(0.3)^1(0.5)^3 = 0.0015$ .

There are  $\frac{6!}{2!1!3!} = 60$  such sequences.

The probability **x** is of type (2, 1, 3) is  $(0.0015) \cdot 60 = 0.09$ .

hhtt	0.0352	tttt	0.0039

#### Observations

As *N* increases, there is an increasing spread of probabilities

The most likely single sequence will always be the all h's

However, for N = 4, the most likely sequence type is 3 h's and 1 t

Not surprising because  $3 = N \cdot p_h$ , pretty much average case.

## Symbol Frequency in Long Sequences

To judge if a sequence is typical/average, a natural question to ask is:

How often does each symbol appear in a sequence  $\mathbf{x}$  from  $X^N$ ?

Intuitively, in a sequence of length N, let  $a_i$  appear for  $n_i$  times. Then **in expectation** 

$$n_i \approx N \cdot P(a_i)$$

Note  $p_i = P(a_i)$ , and

$$P(\mathbf{x}) = P(a_1)^{n_1} P(a_2)^{n_2} \dots P(a_l)^{n_l} \approx p_1^{Np_1} p_2^{Np_2} \dots p_l^{Np_l}$$

## Symbol Frequency in Long Sequences

To judge if a sequence is typical/average, a natural question to ask is:

How often does each symbol appear in a sequence  $\mathbf{x}$  from  $X^N$ ?

Intuitively, in a sequence of length N, let  $a_i$  appear for  $n_i$  times. Then **in expectation** 

$$n_i \approx N \cdot P(a_i)$$

Note  $p_i = P(a_i)$ , and

$$P(\mathbf{x}) = P(a_1)^{n_1} P(a_2)^{n_2} \dots P(a_l)^{n_l} \approx p_1^{Np_1} p_2^{Np_2} \dots p_l^{Np_l}$$

So the *information content*  $-\log_2 P(\mathbf{x})$  of that sequence is approximately

$$-p_1 N \log_2 p_1 - \ldots - p_l N \log_2 p_l = -N \sum_{i=1}^l p_i \log_2 p_i = NH(X)$$

We want to consider elements  $\mathbf{x}$  that have  $-\log_2 P(\mathbf{x})$  "close" to NH(X)

#### Typical Set

For "closeness"  $\beta > 0$  the typical set  $T_{N\beta}$  for  $X^N$  is

$$T_{N\beta} \stackrel{\text{def}}{=} \{ \mathbf{x} : \left| -\log_2 P(\mathbf{x}) - NH(X) \right| < N\beta \}$$
$$= \left\{ \mathbf{x} : \left| -\frac{1}{N} \log_2 P(\mathbf{x}) - H(X) \right| < \beta \right\}$$

Union of types

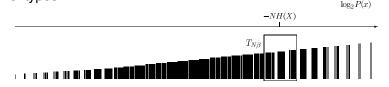

We want to consider elements **x** that have  $-\log_2 P(\mathbf{x})$  "close" to NH(X)

#### Typical Set

For "closeness"  $\beta > 0$  the typical set  $T_{N\beta}$  for  $X^N$  is

$$T_{N\beta} \stackrel{\text{def}}{=} \{ \mathbf{x} : \left| -\log_2 P(\mathbf{x}) - NH(X) \right| < N\beta \}$$
$$= \left\{ \mathbf{x} : \left| -\frac{1}{N} \log_2 P(\mathbf{x}) - H(X) \right| < \beta \right\}$$

Union of types

What when  $\beta = 0$  (and replace < by  $\le$ )?

Criterion based on information content. Other criterion (KL divergence)?

The name "typical" is used since  $\mathbf{x} \in T_{N\beta}$  will have roughly  $p_1 N$  occurrences of symbol  $a_1, p_2 N$  of  $a_2, \ldots, p_K N$  of  $a_K$ .

x lo	$g_2(P(\mathbf{x}))$

1111111111	-65.9
1.11	-56.4
11	-53.2
	-43.7
111	-46.8
1.1.1.1	-56.4
11111111111111	-37.3
1	-43.7
111	-56.4
	-37.3
.11111111	-56.4
111111.1.11	-59.5
11111111	-46.8
	-15.2
	-332.1

Randomly drawn sequences for P(1) = 0.1. Note:  $H(X) \approx 0.47$ 

**Properties** 

Typical sequences are nearly equiprobable: Every  $\mathbf{x} \in T_{N\beta}$  has

$$2^{-N(H(X)+\beta)} \le P(\mathbf{x}) \le 2^{-N(H(X)-\beta)}$$
.

Variation is small when  $\beta$  is small

Number of sequences in the typical set: For any N,  $\beta$ ,

$$|T_{N\beta}| \leq 2^{N(H(X)+\beta)}.$$

Typical sets Def-TNB = {X: 1-108, P(X) - NH(X) | < NB3 [ Recall 1916 for b>0]
-bcacb 1-6092 P(X) - NH(X) (NB -NB < - log\_ p(x) - NH(x) < NB - wg2(p(x) < N(H(x)+1 +N(H(x)-B) <- log, p(x)  $p(x) > \frac{-N(H(x))}{2}$ -N(H(x)-B)> 609, P(z) -N(H(X)-B)> P(X)

#### Proof of Cardinality Bound

For every  $\mathbf{x} \in T_{N\beta}$ ,

$$p(\mathbf{x}) \geq 2^{-N(H(X)-\beta)}$$
.

Thus,

$$1 = \sum_{\mathbf{x}} p(\mathbf{x})$$

$$\geq \sum_{\mathbf{x} \in T_{N\beta}} p(\mathbf{x})$$

$$\geq \sum_{\mathbf{x} \in T_{N\beta}} 2^{-N(H(X) - \beta)}$$

$$= 2^{-N(H(X) - \beta)} \cdot |T_{N\beta}|.$$

Thus

$$|T_{N\beta}| \leq 2^{N(H(X)+\beta)}$$

Most Likely Sequence

The most likely sequence may not belong to the typical set

e.g. with  $p_h = 0.75$ , we have

$$-\frac{1}{4}\log_2 P(\text{hhhh}) = 0.4150$$

whereas H(X) = 0.8113

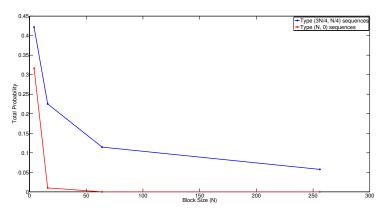

The most likely single sequence  $\rightarrow hhhh$ 

The most likely single sequence type  $\rightarrow$  {hhht, hthh, ...}

Most Likely Sequence

Probability of most likely sequence decays like  $(p_h)^N$   $(p_h = 0.75)$ 

Sequences with  $N \cdot p_h$  heads contain much more total probability mass

Blue curve corresponds to typical set with  $\beta = 0$ . What if  $\beta > 0$ ?

# Asymptotic Equipartition Property Eventually Equally Divided Informally

## Asymptotic Equipartition Property (Informal)

As  $N \to \infty$ ,  $\log_2 P(x_1, \dots, x_N)$  is close to -NH(X) with high probability.

For large block sizes "almost all sequences are typical" (i.e., in  $T_{N\beta}$ )

$$n(r)P(\mathbf{x}) = \binom{N}{r}p_1^r(1-p_1)^{N-r} = \binom{0.14}{0.08} \begin{pmatrix} 0.04 & 0.02 & 0.04 & 0.035 & 0.035 & 0.035 & 0.035 & 0.035 & 0.025$$

Probability sequence **x** has *r* heads for N = 100 (left) and N = 1000 (right). Here P(X = head) = 0.1.

Formally

## Asymptotic Equipartition Property

If  $x_1, x_2, \ldots$  are i.i.d. with distribution P then, in probability,

$$-\frac{1}{N}\log_2 P(x_1,\ldots,x_N)\to H(X).$$

In precise language:

$$(\forall \beta > 0) \lim_{N \to \infty} p\left(\left|-\frac{1}{N}\log_2 P(x_1,\ldots,x_N) - H(X)\right| < \beta\right) = 1.$$

Exactly the probability of  $\mathbf{x} \in T_{N\beta}$ .

Formally

#### Asymptotic Equipartition Property

If  $x_1, x_2, \ldots$  are i.i.d. with distribution P then, in probability,

$$-\frac{1}{N}\log_2 P(x_1,\ldots,x_N)\to H(X).$$

In precise language:

$$(\forall \beta > 0) \lim_{N \to \infty} p\left(\left|-\frac{1}{N}\log_2 P(x_1,\ldots,x_N) - H(X)\right| < \beta\right) = 1.$$

Exactly the probability of  $\mathbf{x} \in T_{N\beta}$ .

Recall definition: for random variables  $v_1, v_2, ...,$  we say  $v_N \to v$  in **probability** if for all  $\beta > 0$   $\lim_{N \to \infty} P(|v_N - v| > \beta) = 0$ 

Here  $v_N$  corresponds to  $-\frac{1}{N} \log_2 P(x_1, \dots, x_N)$ .

Comments

#### Why is it surprising/significant?

For an ensemble with binary outcomes, and low entropy,

$$|T_{N\beta}| \leq 2^{NH(X)+\beta} \ll 2^N$$

i.e. the typical set is a small fraction of all possible sequences

AEP says that for N sufficiently large, we are virtually guaranteed to draw a sequence from this small set

Significance in information theory

Proof

Since  $x_1, \ldots, x_N$  are independent,

$$-\frac{1}{N}\log p(x_1,\ldots,x_N) = -\frac{1}{n}\log \prod_{n=1}^N p(x_n)$$
$$= -\frac{1}{N}\sum_{n=1}^N \log p(x_n).$$

Let 
$$Y=-\log p(X)$$
 and  $y_n=-\log p(x_n).$  Then,  $y_n\sim Y,$  and  $\mathbb{E}[Y]=H(X).$ 

But then by the law of large numbers,

$$(\forall \beta > 0) \lim_{N \to \infty} \rho \left( \left| \frac{1}{N} \sum_{n=1}^{N} y_n - H(X) \right| > \beta \right) = 0.$$
